The Nepal Multiple Indicator Cluster Survey (MICS) is an international multi-purpose household survey. A total sample of 512 enumeration areas and 12,800 households was selected for the survey. It was designed to provide estimates for many indicators on the situation of children and women.
	Rural	Urban
👩 Menstrual Hygiene % of women using appropriate menstrual hygiene materials	96.5 %	92.8 %
% of women with a private place to wash and change	83.1 %	88.6 %

The indicator is based on the estimated average number of people expected to be exposed to perennial river floods per year. It results from the combination of the perennial flood hazard zones as defined by the perennial flood hazard map (25-year return period) and the total population living in the exposed areas as per the population density map. The expected number of people exposed in the hazard zone in one year is the yearly average of the total population living in the exposed area.

The total dependency ratio is the ratio of the sum of the population aged 0-14 and that aged 60+ to the population aged 15-59. The ratio is presented as number of dependants per 100 persons of working age (15-59).

The classification is based on quantile distribution of the calculated values at municipality level. The map shows the relative classification across the country.

Dalit Population: Dalits (the lowest strata of the Hindu caste system) are considered "untouchable" and encounter systemic social and economic exclusion

GDI: It measures achievements in the same basic capabilities (dimensions) as the Human Development Index but takes into consideration inequality in achievements between women and men

GEM: It seeks to determine how much women have been empowered or enfranchised to take part in different aspects of public life in comparison with men
Inequality is calculated taking average of Dalit population data, Gender Development Index (GDI) and Gender Empowerment Measure (GEM).

Note* :
This is a living document. We will be continuously editing and updating with revisions..

To account for increased vulnerability during the recovery period after a disaster, households affected by recent shocks in the past five years are considered. The affected households from the most recent year are considered fully while affected households from the previous years are scaled down with the factor 0.8, 0.6, 0.4, and 0.2 for the second, third, fourth, and fifth year, respectively, assuming that recovery decreases vulnerability progressively.
